INTRODUCTION

From 2002-2005, we collected data in Limpopo Province, at the Agincourt Demographic Surveillance Site, and in Khayelitsha, a township outside of Cape Town, through the auspices of Philani Nutrition and Development Project. Our work was funded by the National Institute on Aging under grant numbers R01 AG20275-01, P01 AG05842-14, and P30 AG024361.

We used integrated health and economic surveys in South Africa, to investigate the links between health status and economic status. Our survey instruments collected data on a range of traditional and non-traditional measures of well-being including income and consumption, measures of health status (including mental health), morbidity, crime, social connectedness, intra-household relationships, and direct hedonic measures of well-being.

In 2002, there was a cross-sectional study conducted in Agincourt. Random household selection was stratified by age-eligibility for the Old Age Pension and nationality. In 2004, there was a second cross-sectional study conducted in Agincourt. Random selection of households was stratified on the basis of both citizenship, (South African or Mozambican), and whether or not a death had occurred in the household.

The study in Khayelitsha was longitudinal. Part 1 of the first wave was conducted in 2002; part 2 of the first wave was conducted in 2003. In 2004, the households who had been interviewed in 2002 were re-interviewed (if they were willing and if they could be found), for part 1 of the second wave. In 2005, the households who were interviewed in 2003 were re-interviewed (if they were willing and if they could be found), for part 2 of the second wave.

For all of the studies, the methodology for conducting the surveys was the same. The questions varied some from year to year. The crosswalk (see table of contents) identifies these variations.

In 2002, there were separate adult modules for younger and older adults. In subsequent years, there was simply one questionnaire for all adults.

In study years 2003, 2004, and 2005, detailed questions in the household questionnaire about the impact of the most recent death in the household were asked of the most knowledgeable household member.

Household Questionnaire:

The most knowledgeable household member (khhm) was the initial person interviewed within the household. He or she would list all of the members of the household. This list of household members was then used as a guide for the entire interview process. The khhm first answered questions about the individual members of the household: age, gender, education, marital status, is that person's partner in the household, is that person's parent in the household. Additionally, the khhm was asked about the source and amount of income of each household member.

Summary information was gathered from the khhm about the household members who had died and the household members who had moved. In study years starting in 2003, detailed questions were posed about the effect the most recent death had on the household.

Detailed questions were asked of the khhm about the living conditions: is there a toilet, is there running water, do you have a stove, a phone. Questions about household expenditures were asked: how is the money spent on health care, on children's schooling expenses, etc.

Adult Questionnaire:

In 2002, there were two separate adult questionnaires. One questionnaire was for adults whose ages fell between 18 and 54; the second questionnaire was for adults 55 years old and up. In subsequent study years there was one questionnaire for adults 18 and older. Every adult from the household, who was available and willing to, answered these questions. Questions about age, marital status, number of living children, and number of children who have died were included. Detailed questions were asked about their sources of income and their expenditures. For older adults, there were questions about pensions and grants, for mothers there were questions about childcare grants. Individuals described the type of jobs they held over the years, how much money they earned and how they spent that money. Detailed health questions were posed; both physical and mental health issues were covered. Physical measurements were taken of the individuals interviewed: their height, weight, waist size; blood pressure and pulse.

Child Questionnaire:

The parent or guardian of each child was questioned about the child. Questions included: birth weight, history of breastfeeding and health of the child. With the parent's or guardian's permission, the child's height and weight were measured. Detailed information was recorded about the child's immunization history.

SAMPLING DESIGN FOR KHAYELITSHA STUDIES

Khayelitsha 2002 and 2004

In 1994, Ingrid le Roux conducted a census of dwellings in Khayelitsha and surveyed a random sample of households from that census. We used the random sample of households surveyed in 1994 to draw a random sample of households to survey in 2002, with a follow up survey in 2004. In total we interviewed members of 203 households in 2002, and 165 households in 2004. The majority of interviews in 2002 were conducted between May and September. The majority in 2004 were conducted between March and July.

Khayelitsha 2003 and 2005

The second part of the Khayelitsha panel is a stratified random sample of 300 households. The township was divided into sampling blocks, and aerial photographs were used to count the number of dwellings in each block. 15 sampling blocks were then selected, with probability proportional to the number of dwellings in each block. A total of 20 households were then randomly sampled within each block. In 2005, 264 of the original 2003 households, and 7 split off households from the original 300 were interviewed. The majority of interviews in 2003 were conducted between March and September. The majority in 2005 were conducted between February and July.

SAMPLING DESIGN FOR AGINCOURT STUDIES

The Agincourt Health and Population Unit (AHPU) is an educational and research unit located within the School of Public Health at the University of the Witwatersrand, South Africa. Since 1992, AHPU has been collecting information on birth, death and migration for all individuals identified as members of the approximately 11,700 households under surveillance in a rural sub-district in (what is now) Mpumalanga Province, South Africa. (For more information on the Agincourt Unit, see <http://web.wits.ac.za/Academic/Health/PublicHealth/Agincourt/>.) The area is home to South Africans and Mozambicans, the latter group settling here legally during the civil war in Mozambique. Most Mozambicans here have permanent residency status which, according to the South African Constitutional Court, allows them access to government transfers. However, it is more difficult for Mozambicans to access government grants, largely because they lack the documents necessary to do so.

Agincourt 2002:

Sample selection was to extract a sample of households, stratified by age-eligibility for the Old Age Pension and nationality. Age eligibility is defined as having either a woman aged 60 and older or a man aged 65 and older within the household.

The frame from which the sampling was done was provided by the 2001 census round of the Agincourt demographic surveillance system.

The sampling design for Agincourt 2002 had the following characteristics:

1. The villages within the population were stratified into two: a set of “Mozambican villages” and a set of “South African” ones.
2. 11 villages were selected, 4 “Mozambican” and 7 “South African” ones. Villages were selected with probability proportional to number of households.
3. The households within each village were assigned to two strata: age-eligible households and non-age-eligible ones.
4. Within each selected Mozambican village twenty households were selected at random, ten from each stratum. In each South African village, thirty households were selected, twelve from the “age-eligible” stratum and eighteen from the “non-age-eligible” stratum.

The final sampling design was:

Strata	SA villages	Mozambican villages
age-eligible	84	40
not age-eligible	126	40

1. We did not explicitly stratify on nationality, but did so implicitly via the villages. This was not only because we were not 100% confident of the “nationality” identifiers, but also because a clustered design seemed advisable in any event. Clustering was decided on because it would make the logistics of fieldwork easier and because cluster effects might be

interesting in their own right. Location is related both to social factors (“Mozambican” villages are somewhat stigmatized) and to geographical ones (there are differences in microclimates and hence crop patterns and also in access to infrastructure)

2. The design ensured that we would have at least twenty households in each cluster which should ensure that some of these cluster effects could be taken into account.
3. The final sample size was 290 households.

The sampling frame for the selection of the villages:

The Agincourt Demographic Surveillance System has information on 21 villages. These formed the initial population from which our sample was drawn. Prior to sampling we excluded four villages from consideration:

- The RDP Housing project
The reason for excluding this settlement was that the dwelling units are apparently not the base of a “household” in the sense in which we wanted to investigate it in this project. Apparently many households send one or two junior members to occupy the RDP house (to maintain a claim to the property), but most of the household activities remain centered on dwellings elsewhere within the study site. It seemed sensible, therefore, to exclude the housing project from consideration.
- Ireagh A, Ireagh B and Kildare A
We were requested by Mark Collinson, the fieldwork manager of the Agincourt Health and Population Unit, not to include these villages in our sample, since other studies would be run (or were currently running) in these villages. The grounds for exclusion were that:
 - Overstressing villages might contaminate the field results from our and other studies
 - It might make fieldwork in future studies more difficult

There were no visible differences between the excluded villages and the other “South African” villages that did not fall within the range of sampling variability.

Stratification within villages by age-eligibility and selection of households

All households within the selected villages were assigned to one of two strata: age-eligible and non-age-eligible. This was done on the basis of the information available in the data base. Age eligibility was calculated as at the 23rd January 2002 (the date on which the sampling was done).

Sampling within each of the strata was done by means of simple random sampling, without replacement.

Sampling weights:

Combining the village selection probabilities with the conditional selection probabilities, we calculated the overall inclusion probabilities of households in each of the strata and hence the appropriate inflation factors. This was carried out for us by Martin Wittenberg at the University of Cape Town. These inflation factors are included in the household data set under the name “Hweight.”

Sampling weights for households in each stratum

Village Number	Primary Nationality in Village	Inflation factors	
		Age-eligible for pension?	
		No	Yes
12	MZ	24.391	9.973
17	MZ	22.961	10.059
19	MZ	19.197	8.506
20	MZ	13.717	5.062
1	SA	55.305	36.425
3	SA	48.013	30.695
8	SA	47.758	27.207
11	SA	51.749	32.437
13	SA	39.061	26.821
14	SA	38.745	17.972
15	SA	39.407	23.470

Procedures for dealing with refusals and households that cannot be located:

The procedures above were followed for extracting the sample. In practice it may not be possible to locate the households concerned, or the households may refuse to be interviewed. The following procedures will be used in these cases:

1. In the case of a refusal, the household to the right will be interviewed
2. If the dwelling can be located, but the household within it has changed, we will interview the new residents at that dwelling
3. If the dwelling cannot be located, either because the map has been badly drawn or because the structure no longer exists, a replacement household will be drawn from the same stratum.

Agincourt 2004:

Sample design

In January 2004, using Agincourt Health and Population Unit (AHPU) census information, we drew a stratified random sample of 475 households across all villages in the Agincourt Demographic Surveillance Site, with stratification on both citizenship (South African versus Mozambican) and on whether the household had lost a member to death in the period from June 1, 2002 to May 31, 2003. By “Mozambican household” in the sample design we mean that the nationality of the head of household is Mozambican. Our sample design and the actual number of households interviewed in each stratum are shown in Box 1.

Box 1. Sample design for Agincourt field work

	Number of households	South African households	Mozambican households
No death in household	Design	190	127
	Actual	187	127
Death in household	Design	95	63
	Actual	96	63

The sample was designed to be 60 percent South African, and 40 percent Mozambican. In execution, slightly fewer South African households without a death were interviewed (187 instead of 190), and one extra South African household with a death was interviewed (96 instead of 95).

These discrepancies were the result of confusion over which households were considered to have a ‘complete’ interview in cases where the head of household refused to be interviewed. The survey is composed of a household module, to be completed by a knowledgeable household member; an adult module, to be completed by each member aged 18 or older; and a child module, to be completed for each child aged 12 or younger. Some adult household members were migrants who were not in the field site to be interviewed (although the field team made a great effort to make appointments with the household to return at month-end, or at Easter, to interview returning migrants). In addition, some adult members refused to be interviewed. We decided that if the household module was completed, and at least one adult was interviewed, the household had a ‘complete’ interview.

In the South African-Death Stratum, an extra household was interviewed because the household head came home for Easter, after the rest of the household had been interviewed, and refused to participate. The field team then interviewed a replacement household, but need not have: we had made a decision that if the head refused to participate, but did not stop other members from doing so, then that household’s information would be used. However, if a returning head refused to let any members participate (even if they had already been interviewed), we did not use that household in our analysis.

Sampling weights

We calculate household inflation factors as the inverse of the product of the probability that an individual household i in strata s was chosen times the number of households surveyed in strata s :

$$w_{is} = (n_s \pi_{is})^{-1}.$$

(See Angus Deaton, *Analysis of Household Surveys*, 1997, page 50, for details.)

The inflation factors, calculated using actual sample sizes from Box 1, and the number of households of each type in the field site, are given in Box 2. These inflation factors are also included in the household level data file under the name “**Hweight**.”

Box 2. Inflation factors for the 2004 data

	Type of household	Number of households in the field site	Inflation factor
No death in household	South African	7927	42.39037
	Mozambican	3107	24.46457
Death in household	South African	420	4.375000
	Mozambican	192	3.047619

THE DATA

General Information:

For each study (or studies in the case of Khayelitsha), the responses to the questionnaires were keyed, and then rekeyed by two separate groups. The original keyed data was compared to the rekeyed data. When there was a mismatch, the paper documents were consulted and the correct answer identified. Corrections were applied to the original keyed data using Stata 10.

The datasets were created from the responses to the questionnaires based on the logic detailed below.

Household Questionnaire responses are in the following datasets:

hh_h: This datasets include all of the responses to the questions asked of the khhm at the household level in the household module. This includes household expenditures, description of household contents (including type of toilet and water supply). The cross walks for the different studies will tell which specific questions in each survey are included in the hh_h dataset. There is one record for each household.

hh_p: This dataset includes the responses to the questions asked of the khhm about individual member of the household. These questions were asked in section A.1 of the household questionnaire and included information about age, gender, relationship to household head, education level and marital status. There is a separate record for each member of the household.

hh_mrd: The khhm in every year but 2002, answered detailed questions about the member of the household who had died most recently. These questions appeared within section A.3 of the household questionnaire. For the Most Recent Death, there is one record for each household that experienced the death of a resident.

hh_comrd: If the person who died most recently in the household had children under 18, the khhm was asked to list them and answer a few questions about these children. These questions appeared within section A.3 of the household questionnaire. This dataset on Children Of the Most Recent Death include a record for each child under 18 of the resident who died most recently.

hh_died: The khhm was asked to list all of the household residents who died within the 5 years prior to the study. In the second wave of the Khayelitsha study, the khhm was asked to list the residents who died since they had been interviewed the first time. These questions appeared within section A.3 of the household questionnaire. There is one record per each person who died per household.

hh_moved: The khhm was asked to list all of the household residents who moved within the 5 years of prior to the study. In the second wave of the Khayelitsha study, the khhm was asked to list the residents who moved since they had been interviewed the first time. These questions appeared within section A.4 of the household questionnaire. There is one record per each person who moved per household.

Adult Questionnaire responses are in the following dataset:

ad: The individual household members who were over 18 were asked detailed questions from the Adult Questionnaire. In the 2002 surveys there were two separate questionnaires, one for individuals from 18 to 54 and the second for individuals 55 and older. These two datasets were combined into the ad dataset. Use the crosswalk for the appropriate study year to see how the questions cross-correlate from the younger adult to the older adult questionnaires. This dataset has one record per each adult in the household who was willing to be part of the survey.

Child Questionnaire responses are in the following dataset:

ch: The responses of the parent or guardian of each child in the household are included in this dataset. The height and weight of the child, along with the child's birth weight, and history of breastfeeding are also included. Not included: the immunization history of the child. There is one record per child per household.

Khayelitsha Data:

The Khayelitsha data differ from the Agincourt 2002 and 2004 data in that they are in longitudinal format. Instead of one record per household in the hh_h dataset, there will be two records per household, except in the cases where the household residents refused to be interviewed again or could not be found. What makes each observation unique, then, is the household identification number plus the year the study was conducted. For hh_p, what will make each observation unique will be the year plus the household identification number plus the individual or personal code (pcode).

Khayelithsa variables: hhid and hhid_ind:

Household ID: (hhid)

Study year 2002: 20029999 where 9999 = the original hhid (padded to four digits if necessary)

Study year 2003: 20039999 where 9999 = the original hhid (padded to four digits if necessary)

Study year 2004: 20029999 where 9999 = the original hhid (padded to four digits if necessary)

- Use this ID when the 2004 household is the same as the 2002 household 44449999 where 9999 = the hhid assigned at the time of the study
- Use this ID when the 2004 household interviewed is not the same as the 2002 household interviewed OR the 2004 household was not interviewed at all

Study year 2005: 20039999 where 9999 = the original hhid (padded to four digits if necessary)

- Use this ID when the 2005 household is the same as the 2003 household 55559999 where 9999 = the hhid assigned at the time of the study
- Use this ID when the 2005 household interviewed is not the same as the 2003 household interviewed OR the 2005 household was not interviewed at all

Household indicator: hhid_ind)

The household indicator will only be used on the second year of the study years (2004 and 2005). It will be equal to 0 if this household is the same as the household interviewed in study year1. It will be equal to between 1 and 12 if there are problems.

hhid_old will contains the hhid from study year1 where appropriate

hhid_ind	Label value of hhid_ind
0	Same hh as other study year
1	Not interviewed--hh moved
2	Not interviewed--they refused
3	No one living in house--death, jail, demolition, tenant chased away
4	House sold--new owner
5	Splinter household
6	Interviewed no mems in common with other study year
7	Data lost for hh
10	Not interviewed--wrong hh
11	Not Interviewed--Can't find hh
12	No hh module, head of hh refused

Year variable: This will contain the year that the study was conducted.

PUBLIC RELEASE DATASETS

Agincourt 2002

Agincourt 2002 Household Module Datasets: Most knowledgeable household member answers all questions in the household module (sometimes with the help of a proxy)					
File name	Description	# of households	# of records	Unique Identifier	File Structure
