Sampling

Sampling Procedure

The population was stratified according to nine socio-economic area types. The allocation was roughly proportional to the adjusted 1991 population census figures. Multistage cluster (probability) sampling was used to draw the respondents, using the adjusted 1991 population census figures as a sampling frame. Census enumerator areas and similar areas were used as the clusters in the penultimate sampling stage, from which an equal number of households were drawn. All the clusters were drawn from the final clusters with equal probability (systematically). The respondents were drawn at random from qualifying household members.
