Sampling

Sampling Procedure

The sample for the KDHS is based on the National Sample Survey and Ewduation Programme (NASSEP) master sample maintained by the CBS. The KDHS sample is national in coverage, with the exclusion of North Eastern Province and four northern districts which together account for only about five percent of Kenya's population. The KDHS sample was designed to produce completed interviews with 7,500 women aged 15-49 and with a subsample of 1,000 husbands of these women.

The NASSEP master sample is a two-stage design, stratified by urban-rural residence, and within the rural stratum, by individual district. In the first stage, 1979 census enumeration areas (EAs) were selected with probability proportional to size. The selected EAs were segmented into the expected number of standard-sized clusters, one of which was selected at random to form the NASSEP cluster. The selected clusters were then mapped and listed by CBS field staff. In rural areas, household listings made between 1984 and 1985 were used to select the KDHS households, while KDHS pretest staff were used to relist households in the selected urban clusters.

Despite the emphasis on obtaining district-level data for phoning purposes, it was decided that reliable estimates could not be produced from the KDHS for all 32 districts in NASSEP, unless the sample were expanded to an unmanageable size. However, it was felt that reliable estimates of certain variables could be produced for the rural areas in the 13 districts that have been initially targeted by the NCPD: Kilifi, Machakos, Meru, Nyeri, Murang'a, Kirinyaga, Kericho, Uasin Gishu, South Nyanza, Kisii, Siaya, Kakamega, and Bungoma. Thus, all 24 rural clusters in the NASSEP were selected for inclusion in the KDHS sample in these 13 districts. About 450 rural households were selected in each of these districts, just over 1000 rural households in other districts, and about 3000 households in urban areas, for a total of almost 10,000 households. Sample weights were used to compensate for the unequal probability of selection between strata, and weighted figures are used throughout the remainder of this report.

Response Rate

A total of 9,836 households were selected in the Kenya Demographic and Health Survey. Of these, 8,343 were identified as occupied households during the fieldwork and 8,173 were successfully interviewed. Respondents for the individual interview were women aged 15-49 who had spent the night before the interview in the selected household. In the interviewed households, 7,424 eligible women were identified and 7,150 were successfully interviewed. In general, few problems were encountered during the interviewing and the response rate was high--98 percent for households and 96 percent for individual female respondents. In addition, 1,116 husbands were interviewed out of a total of 1,397 eligible, for a response rate of 81 percent. Eligible husbands were defined as those who spent the night before the interview in the selected households and whose wives were successfully interviewed. Every other household was considered eligible for the husband interview.

The distribution of all women by province indicates only minor differences among the three sources of data. For purposes of comparison, Respondents are classified into 4 educational categories, according to the highest grade attained at each level. These categories are: no education, 1-4 years, 5-8 years, and 9 or more years. The data show a strong increase in the educational attainment of women over time. The proportion of women with no education declined from 44 percent in 1977/78 to 25 percent in 1989. The proportion of women who have 5 to 8 years of education is higher in 1989 (43 percent) than in 1984 (32 percent) and 1977/78 (27 percent).

Questionnaires

Overview

The KDHS utilised three questionnaires: a household questionnaire, a woman's questionnaire, and a husband's questionnaire. The first two were based on the DHS Programme's Model "B" Questionnaire that was designed for low contraceptive prevalence countries, while the husband's questionnaire was based on similar questionnaires used in the DHS surveys in Ghana and Burundi. A two-day seminar was held in Nyeri in November 1987 to develop the questionnaire design. Participants included representatives from the Central Bureau of Statistics (CBS), the Population Studies Research Institute at the University of Nairobi, the Community Health Department of Kenyatta Hospital, and USAID. The decision to include a survey of husbands was based on the recommendation of the seminar participants. The questionnaires were subsequently translated into eight local languages (Kalenjin, Kamba, Kikuyu, Kisii, Luhya, Luo, Meru and Mijikenda), in addition to Kiswahili.

DATA COLLECTION NOTES

TRAINING

In order to test the quality of the translations, as well as to check other aspects of survey design, a pretest was conducted in July and August 1988. Sixteen female and 8 male interviewers were recruited and trained for two weeks in July 1988 by NCPD, CBS and IRD/DHS staff. They were then grouped into teams, one for each of the eight local languages, and travelled to selected areas in various parts of the country where those languages are spoken. Officers from NCPD and CBS accompanied the teams as supervisors. The interviewers carried out about 200 pretest interviews with women and somewhat fewer with husbands. After the pretest, the questionnaires were modified slightly based on the pretest comments.

Training for the main survey was held in Machakos from October 26 to November 17. Participants included 26 people who had conducted the pretest and 55 new recruits, for a total of 81. Most of the trainees had "O" level education, while a few had "A" level. Training consisted of a combination of classroom lectures, demonstration interviews in front of the whole group, mock interviews in smaller groups, practice in interviewing in the local languages, a written examination, and, during the final three days, field practice interviews in households outside the town center. Training was conducted by 5 officers from the NCPD and one from the CBS.

Towards the end of the course, the trainers met and determined who would be the supervisors, field editors, interviewers and data processing staff. For the most part, the former pretest interviewers were selected as supervisors and field editors. They received special training in how to scrutinize questionnaires for accuracy, completeness, and consistency, while supervisors were taught how to read maps and use the household listing form to find the selected households.

FIELDWORK

KDHS field staff were divided into 9 full-sized teams (one for each of the eight vernaculars and two for the Kikuyu language), each with a supervisor, a field editor, 4 or 5 female interviewers, and one male interviewer. Although the questionnaires were not translated into Maasai, a special small team, consisting of a supervisor and two Maasai-speaking interviewers was formed to cover the few clusters selected in Narok and Kajiado Districts. The first three teams began data collection in December 1988. The delay in sending out the other teams was due to the lack of vehicles. By mid-February 1989, all the teams had been launched. Field work was co-ordinated by NCPD Headquarters and most teams were accompanied at least initially by NCPD officers, who also made periodic supervisory field trips. The CBS full-time enumerators and supervisors were also utilized to help locate the selected sample points and households and in some areas, the District Statistical Officers assisted in supervising the teams and providing communication and logistical support.'

Due to attrition in field staff during the first few months of the survey, NCPD recruited some eight replacements in early February 1989. After a one-week training at NCPD Headquarters, the new recruits were sent to their respective teams to observe their colleagues and conduct some practice interviews before being fully integrated into the team.

Data Processing

Data Editing

Data processing staff for the KDHS consisted of five data entry clerks, two data entry supervisors and a control clerk who logged in questionnaires when they arrived at the office. The staff was supervised by two NCPD officers with periodic assistance from IRD staff. All the data processing staff completed the interviewer training course in November 1988 and received further instruction in data processing from the IRD staff.

Three IBM-compatible desktop microcomputers were installed in a temporary office on the Kenyatta National Hospital compound and were used to process the data. The Integrated System for Survey Analysis (ISSA) program was used for data entry, editing and tabulations. The supervisors and the NCPD officers were responsible for supervising data entry, and for resolving inconsistencies in questionnaires detected during secondary machine editing.

Data processing started in February 1989, once a sufficient number of questionnaires had been returned to Nairobi. Data entry was completed in early June and tabulations for the preliminary report were run in mid-June, two weeks after the last interview took place. The preliminary report was printed in July, tabulations for the final report were also produced in July, and this report was drafted in August and September.

Data Appraisal

Estimates of Sampling Error

The sample of women selected in the KDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each one would have yielded results that differed somewhat from the actual sample selected. The sampling error is a measure of the variability between all possible samples; although it is not known exactly, it can be estimated from the survey results. Sampling error is usually measured in terms of the "standard error" of a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which one can be reasonably assured that, apart from non-sampling errors, the true value of the variable for the whole population falls. For example, for any given statistic calculated from a sample survey, the value of that same statistic as measured in 95 percent of all possible samples with the same design (and expected size) will fall within a range of plus or minus two times the standard error of that statistic.

If the sample of women had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the KDHS sample design depended on stratification, stages, and clusters; consequently, it was necessary to utilize more complex formulas. The computer package CLUSTERS was used to assist in computing the sampling errors with the proper statistical methodology.

In addition to the standard errors, CLUSTERS computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample; a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design.

Sampling errors are presented in Table B.2 through B.4 in the Appendix to the Final Report for 45 variables considered to be of major interest. Results are presented for the whole country and for urban and rural areas. In Tables B.5 through B.11, results are presented by province for 30 variables. Finally, Table B.12 contains sampling errors for current contraceptive use for the 13 targetted districts. For each variable, the type of statistic (mean, proportion) and the base population are given in Table B.1. For each variable, Tables B.2 through B.12 present the value of the statistic, its standard error, the number of unweighted and weighted cases, the design effect, the relative standard error, and the 95 percent confidence limits.

The confidence interval has the following interpretation. For current use of family planning (CURUSE), the overall proportion of married women using is 0.269 or 26.9 percent and its standard error is 0.010. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., $0.269 \pm (2 \times 0.010)$, which means that there is a high probability (95 percent) that the true contraceptive prevalence rate falls within the interval of 0.250 to 0.288 (25 to 29 percent).

The relative standard error for most estimates for the country as a whole is not large, except for estimates of very small proportions. The magnitude of the error increases as estimates for subpopulations such as particular provinces or districts are considered. For contraceptive prevalence, for example, the relative standard error (as a percentage of the estimated proportion) for the whole country, urban areas, Nairobi and Kilifi District is, respectively, 3.6 percent, 6.2 percent, 7.6 percent, and 23.3 percent. By district, this means that the prevalence rate of 31.3 for Murang'a District cannot be said with certainty to differ from the rate of 20.2 for Kisii District, since the confidence intervals overlap. Similarly, the difference between the rates for Kirinyaga (52.2 percent) and Machakos Districts (40.4 percent) might be explained by sampling error.

Other forms of Data Appraisal

Nonsampling error is due to mistakes made in carrying out field activities, such as failure to locate and interview the correct household, errors in the way questions are asked, misunderstanding of the questions on the part of either the interviewer or the respondent, data entry errors, etc. Although efforts were made during the design and implementation of the KDHS to minimize this type of error, nonsampling errors are impossible to avoid and difficult to evaluate analytically.
