Sampling

Sampling Procedure

Based on the 1987 Malawi Population and Housing Census, the country is demarcated into 8,652 enumeration areas (EAs) of roughly equal population size. This sampling frame of census EAs was stratified by urban and rural areas within each of the three administrative regions, making six sampling strata in total. Within each sampling stratum, districts were geographically ordered, thereby providing additional implicit stratification.

The MDHS sample of households was selected in two stages. First, 225 EAs were selected from the 1987 census frame of EAs with probability proportional to population size. The distribution of selected sample points (EAs) is shown in the map of Malawi. The measure of EA size was based on the number of households enumerated during the 1987 census. NSO staff, after being trained in listing procedures and methods for updating maps, were sent to the selected EAs to list all households and produce maps which provided the orientation for later data collection teams in finding selected households. Households in refugee camps and institutional populations (army barracks, police camps, hospitals, etc.) were not listed. In the second stage, a systematic sample of households was selected from the above lists, with the sampling interval from each EA being proportional to its size based on the results of the household listing operation.

In these households, all women age 15-49 years were eligible for interview. Further, a one-in-three systematic subsample of households was drawn, within which both eligible men age 20-54 years and women age 15-49 years were interviewed.

Because the objective of the survey was to produce region-level and urban/rural estimates of some indicators, an oversample of households in the Northern Region and in urban areas was necessary.

Response Rate

The results of household and individual interviews for the urban and rural sample and for Malawi as a whole shows a total of 5,811 households which was selected in the MDHS sample, of which 5,396 were currently occupied. Of the 5,396 occupied households, 5,323 were interviewed, yielding a household response rate of 98.6 percent. Rural and urban response rates at the household level did not differ significantly.

Within the interviewed households, 5020 eligible women (15-49 years) were identified of which 4849 were interviewed, yielding an individual female response rate of 96.6 percent. In the one-in-three subsample of households, 1,288 eligible men were identified, of which 1,151 were successfully interviewed (89.4 percent response). The principal reason for nonresponse among both eligible men and women was the failure to find them at home despite repeated visits to the household. The lower response rate among men than women was due to more frequent and longer-term absence of men. The refusal rate in the MDHS was extremely low (0.1 percent).

Response rates were marginally better in rural areas than in urban areas in the male survey (rural, 90.3 percent; urban, 87.5 percent), but nearly the same in the female survey (rural, 96.5 percent; urban, 96.8 percent).

Weighting

Thus the MDHS sample is not self-weighting at the national level, but it is self-weighting within each of the six region/urban-rural strata.

Questionnaires

Overview

Four types of questionnaires were used: the Household Questionnaire, the Individual Female Questionnaire, the Individual Male Questionnaire, and the Health Services Availability Questionnaire. The contents of these questionnaires were based on the DHS Model B Questionnaire, which is designed for use in countries with a low level of contraceptive use. Modification of the questionnaires was undertaken by NSO in consultation with the Ministry of Health and Macro. The questionnaires were pretested in April 1992.

Data Collection

DATA COLLECTION NOTES

PRETEST

The Household Questionnaire was used to list all the usual members and visitors of selected households. A household is defined as one that consists of one or more persons, related or unrelated, who make common provisions for food, or who regularly take all their food from the same pot or same grainstore (Nkhokwe), or who pool their incomes for the purpose of purchasing food. Persons in a household may live in one or more dwelling units. Information was collected on the characteristics of each person listed, including his/her age, sex, education, and relationship to the head of the household. The main purpose of the Household Questionnaire was to identify women who were eligible for individual interview, namely, those age 15-49 years.

For those women who were either absent or could not be interviewed during the first visit, a minimum of three visits were made before recording nonresponse. Women were interviewed with the individual female questionnaire. In the course of administering the household questionnaire, eligible men, namely, those age 20-54 were also identified. The individual male questionnaire was administered to all men age 20-54 living in every third household in the selected sample. The male questionnaire collected much of the same information found in the female questionnaire, but was considerably shorter because it did not contain questions on reproductive history, and maternal and child health.

During the household listing operation (i.e., before the main survey), one Health Services Availability Questionnaire was completed in each of the 225 MDHS sample points. Leaders in the community provided information that allowed an assessment of the availability of health and family planning services to persons living in the respective localities.

TRAINING

A three-week training course for the main survey was held in July and August of 1992. A total of 80 field staff was trained. The training course consisted of instruction in general interviewing techniques, field procedures, a detailed review of items on the questionnaires, instruction and practice in weighing and measuring children, mock interviews between participants in the classroom, and practice interviews in areas outside MDHS sample points. Only trainees who performed satisfactorily in the training programme were selected for fieldwork. Team leaders were NSO staff who had previously participated in the MDHS pretest.

DATA COLLECTION

The fieldwork for the MDHS was carried out by ten interviewing teams, each consisting of one team leader, one field editor, five female interviewers, one male interviewer and one driver. Additionally, senior NSO staff co-ordinated and supervised fieldwork activities. Data collection began 1 September and was completed on 10 November 1992.

Data Processing

Data Editing

Completed questionnaires were returned to NSO for data processing. The processing operation consisted of office editing, coding of open-ended questions, data entry and editing of errors found by the computer programs. Data entry, editing, and analysis were accomplished on personal computers, using a software program called ISSA (Integrated System for Survey Analysis). Data processing started on 14 September 1992 and was completed on 21 January 1993.

Data Appraisal

Estimates of Sampling Error

Sampling errors, on the other hand, can be measured statistically. The sample of women selected in the MDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each one would have yielded results that differed somewhat from the actual sample selected. The sampling error is a measure of the variability between all possible samples; although it is not known exactly, it can be estimated from the survey results.

Sampling error is usually measured in terms of standard error of a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which one can be reasonably assured that, apart from nonsampling errors, the true value of the variable for the whole population falls. For example, for any given statistic calculated from a sample survey, the value of that same statistic as measured in 95 percent of all possible samples with the same design (and expected size) will fall within a range of plus or minus two times the standard error of that statistic.

If the sample of women had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the MDHS sample design depended on stratification, stages and clusters. Consequently, it was necessary to utilise more complex formulas. The computer package CLUSTERS, developed by the International Statistical Institute for the World Fertility Survey, was used to assist in computing the sampling errors with the proper statistical methodology.

In addition to the standard errors, CLUSTERS computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. CLUSTERS also computes the relative error and confidence limits for the estimates.

In addition to the standard errors, CLUSTERS program also computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample; a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design.

Sampling errors are presented in Tables B.2-B.7 of the Final Report for variables considered to be of major interest. Results are presented for the whole country, for urban and rural areas, and for regions. For each variable, the type of statistic (mean or proportion) and the base population are given in Table B.1. For each variable, Tables B.2-B.7 present the value of the statistic (R), its standard error (SE), the number of unweighted (N) and weighted cases (WN), the design effect (DEBT), the relative standard error (SE/R), and the 95 percent confidence limits.

The confidence limits have the following interpretation. For the mean number of children ever born (EVBORN), the overall average from the sample is 3.482 and its standard error is 0.049. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., $3.482 + (2 \times 0.049)$, which means that there is a high probability (95 percent) that the true average number of children ever born is between 3.383 and 3.580.

The relative standard error for most estimates for the country as a whole is small, except for estimates of very small proportions. The magnitude of the error increases as estimates for subpopulations such as geographical areas are considered. For the variable children ever born (EVBORN), for instance, the relative standard error (as a percentage of the estimated mean) for the entire country and its regional divisions are 1.4 percent, 2.5 percent, 1.9 percent and 2.4 percent, respectively.

Other forms of Data Appraisal

Nonsampling error is the result of mistakes made in implementing data collection and data processing procedures, such as failure to locate and interview the correct household, errors in the way the questions are asked, misunderstanding on the part of either the interviewer or the respondent, data entry errors, etc. Although numerous efforts were made during the design and implementation of the MDHS to minimise this type of error, nonsampling errors are impossible to avoid and difficult to evaluate statistically.
