Sampling

Sampling Procedure

The project is being implemented in 29 rural districts (kabupaten) in East Java. Eight of those 29 districts are participants in the impact evaluation-a total of 2080 households in 160 sub-villages (dusun). The sample is geographically representative and representative of the households in rural East Java.

A total of 160 sub-villages from eight districts are participants in the IE. From each district, 10 treatment and 10 control villages were randomly chosen to participate in the IE. Local government offices from each district gave the IE team a list of at least 30 villages where the program could be implemented. Most district offices gave the IE teams lists of 40-70 villages. These are villages the districts had chosen to participate in the project based on sanitation needs, poverty levels, access to water, and so forth.³ Using a random number generator in STATA, the IE team randomly selected 10 treatment and 10 control villages from each district list. The IE team then sent the list of 20 villages back to the district government office (without telling them which villages had been selected as control and treatment villages). The reason for this is that the project is actually implemented at the dusun, or sub-village level. Villages generally have two to three sub-villages. Wanting the same selection criteria to be used for the selection of sub-village for both the treatment and control villages, the IE team asked each district office to provide the sub-village names for all 20 villages. District offices were told that some would be the treatment and others the control.

Once the IE team received the sub-village lists from the district offices for all 20 villages, the district offices were told which villages were in the treatment group and which ones were in the control group. The district offices committed that they would do everything possible to make sure the treatment dusun were treated and the control dusun remained untreated. There was some concern by local program implementers that the program might spread like "wildfire" and that it would be difficult to deny control villages the program. However, sample sizes were selected based on this possibility and it does not appear that many control villages have been contaminated.

Note: Detail sampling procedure is available in "Scaling Up Rural Sanitation: Findings from the Impact Evaluation Baseline Survey in Indonesia" November 2010 survey report.

Questionnaires

Overview

The following instruments were used to collect the data:

- Household questionnaire: The household questionnaire was conducted in all households and was designed to collect data on household membership, education, labor, income, assets, dwelling characteristics, water sources, drinking water, sanitation, observations of handwashing facilities and other dwelling characteristics, handwashing behavior, child discipline, maternal depression, handwashing determinants, exposure to health interventions, relationship between family and school, and mortality.
- Health questionnaire: The health questionnaire was conducted in all households and designed to collect data on children's diarrhea prevalence, ALRI and other health symptoms, child development, child growth, and anemia.
- Community questionnaire: The community questionnaire was conducted in 120 districts to collect data on community/districts variables.
- Structured observations: Structured observations were conducted in a subsample of 160 households to collect data on direct observation of handwashing behavior.
- Water samples: Water samples were collected in a subsample of 160 households, to identify *Escherichia coli* (E. coli) presence in hand rinses (mother and children), sentinel toy, and drinking water.
- Stool samples: Stool samples were collected in a subsample of 160 households to identify prevalence of parasites in children's feces.

Data Processing

Other Processing

The data files as they are output in CSPro follow the hierarchical structure as established in the data dictionary. These however may not be convenient for the analyst. The WSP requested that the files be integrated into various record level files. The files that are included in the final data base reflect this structure.

However, some analysts may still want the hierarchical level data available in its original record form (as it was during data entry). For that reason, these files are also zipped together and provided in the event that they are desired.

The final data files are provided in STATA format as requested by the WSP.
