Acknowledgments

We thank all those who directly or indirectly contributed to this survey. Its completion would not have been possible without the considerable organizational and intellectual resources of Prof. H. K. R. Amani. The success of the fieldwork is due largely to his skills and persistence, the efforts of three other supervisors, and the work of 31 enumerators in mainland Tanzania and Zanzibar. We also thank Martha Ainsworth, Lucy Goodhart, Pankaj Rawal, and Marisol Ravicz for their collaboration in producing the survey materials. We would also like to acknowledge, with appreciation, comments received on earlier drafts from Patricia Champ, Pedro de Lima, Paul Glewwe, Margaret Grosh, David Guilkey, Philip Hiza, Estelle James, Young Kimaro, Ruth Levine, Jacob van Lutsenburg Maas, Emmanuel Malangalila, Timothy Marchant, Felix Ndaba, Robert Ngong, Mead Over, Bill Shaw, Paul Shaw, Dale Whittington, and John Zayumba. Margaret Grosh and Dean Jolliffe's comments on the final documentation sets and dissemination strategy proved invaluable.

We are very grateful to the Government of Tanzania, particularly to Mr. Mkai and Mr. Mbele from the Bureau of Statistics, and the Government Statistician for providing us with the weights from the National Master Sample. We thankfully recognize the collaboration and support of the Department of Economics of the University of Dar es Salaam.

For their contribution, we thank Dr. Swai and his data entry team, and Kathleen Benson of Office Remedies and her team. Lynn Tsofilias and Joyce Bentzman spent several months coding character variables and correcting the inevitable coding errors and inconsistencies. We also acknowledge the support of the World Bank Resident Mission in Dar es Salaam, especially that of Dr. Emmanuel Malangalila, Motoo Konishi, Roy Southworth, Marayanne Mwankangale, Mercy Sabai, Rosalie Ferrao, and Elizabeth Sakaya. Ms. Sakaya proved invaluable in serving as our liaison with Prof. Amani during the field work and in tracking the questionnaires. Raju Laburam, Lourdes Meliotes, Yordi Seium, and Helena Nkole of World Bank Headquarters helped to solve the innumerable logistical and financial problems we experienced. Mr. Liberatus Shirima--assisted by Mr. Fanuel Senge and Mr. Fernie Kweka--collected most of the district data, and Ethiopia Taddese processed them.

We acknowledge, with thanks, the British Overseas Development Administration, especially William Kingsmill, David Campbell, Anthony Gardner, and David Pedley for their assistance in financing the survey. Additional funding was provided by the Government of Japan and The World Bank. Finally, we thank all the Tanzanian families who so kindly gave their time and energy to respond to the survey questions. This document was edited by Andrew Follmer.

DATA AVAILABILITY

The data sets and documentation can be obtained from:

- (i) Professor H. R. K. Amani at the Department of Economics at the University of Dar es Salaam, Dar es Salaam, Tanzania, if you or your institution are located in Eastern Africa.
- (ii) The Poverty and Human Resources Division of the Policy Research Department at the World Bank, 1818 H Street, N.W., Washington D.C. 20433
- (iii) The Human Resource Division of the Africa Technical Department at the World Bank, 1818 H Street, N.W., Washington D.C. 20433
- (iv) The World Bank Gopher system (Gopher.worldbank.org) after March 15, 1995.
- (v) The World Bank Mosaic system ([Http://www.worldbank.org](http://www.worldbank.org)) after March 15, 1995.

THE WORLD BANK**

DATA AGREEMENT FORM

In receiving these data it is recognized that the data are supplied for use within my organization, and I agree to the following stipulations as conditions for the use of the data:

1. The data are supplied for use at/by _____ and will not be made available to any other organizations or individuals. Other organizations or individuals may request the data directly from the World Bank.
2. Three copies of all publications, conference papers, or other research reports based entirely or in part upon the requested data will be supplied to:

The World Bank
c/o Tanzania HRDS Manuscripts
Population and Human Resources Division
Eastern Africa Department
1818, H Street, N. W.
Washington, D.C. 20433, U.S.A.

3. The researcher will give recognition of the source in all publications, conference papers, and manuscripts with the following statement "The data used in this paper come from a nationally representative survey of 5,000 households in Tanzania. The survey was a joint effort undertaken by the Department of Economics of the University of Dar es Salaam, the Government of Tanzania, and the World Bank, and was funded by the World Bank, the Government of Japan, and the British Overseas Development Agency."

WHY A SURVEY IN TANZANIA?

1. The Population and Human Resources Division of the Eastern Africa Department of The World Bank, in collaboration with the University of Dar es Salaam and the Tanzanian Planning Commission, decided to undertake a survey in Tanzania which would consist of a household survey, a limited community module and a price questionnaire. The objectives of the survey were to provide information regarding the following:

- a. Household use of, and expenditure patterns for, social services;
- b. Reasons for low levels of household investment in education and health services for children;
- c. The distribution of the benefits of public spending for social services and how to improve targeting;
- d. Households' evaluation of the social services available to them;
- e. The potential for demand-side interventions to increase human capital investment directly (especially for girls and the poor); and
- f. The feasibility of repeated national monitoring surveys to assess the impact of future Bank and government projects in the social sectors, and to increase Tanzania's capacity to perform household survey work.

2. This document serves two purposes. First, it is a project completion report, so it outlines the major stages of the Tanzania Human Resource Development Survey (HRDS). It emphasizes the reasons for the survey's success, its shortcomings, and the areas where, if performed differently, it could have obtained better or faster results. Second, together with the questionnaires themselves, it provides information sufficient to allow the reader to use the datasets. This report is organized as follows: Section 2 describes the contents of the questionnaire. Section 3 describes the steps followed in conducting the survey, and Section 4 concludes the paper by presenting what should have been done differently and the major lessons learned from this experience.

3. **Background.** Tanzania maintains a substantial amount of data on its public service delivery systems in health, education, and water supply. However, it has very little population-based information on households' utilization of social services. Social sector projects have been designed from a top-down perspective with little or no information on the behavioral patterns, desires, capabilities, or constraints of the intended beneficiaries. The government and donors have designed social policies and projects in Tanzania on the basis of assumptions regarding household needs and behavior. Policies have been

dominated by efforts to achieve geographical equity in the distribution of a predetermined set of social services. There has been minimal attention given to economic factors, the need to overcome households' constraints in using social services, identification of the beneficiaries of public subsidies, strategies to target those subsidies more effectively, the role of the private and charitable sectors in service delivery, gender issues in the utilization of social services, strategies to effect greater investment by households in the human capital of their children, or to households' assessments of the services they are provided.

4. In addition, there has been a presumption that the government should provide social services directly. Consequently, there is little information regarding how households mix use of public, private, and charitable sources of social services. In short, population-based surveys have not been a significant component of project development, monitoring, or evaluation in the social sectors.

5. **Other Surveys.** In the last three decades, several household budget surveys have been conducted. Some of them have been nationally representative. Others have only covered the rural population, while still others covered only specific regions. Some of these surveys have included data on living conditions, consumption patterns, and income sources. The 1969 and 1976/77 Household Surveys, two rural household surveys in 1980 and 1983, and the 1991 Cornell/ERB Household Survey fall within this category. The two most recent surveys, the 1991 Household Budget Survey and the 1991 Cornell/ERB survey, have collected only economic information, with a few simple questions on expenditures for social services. Three other household surveys have recently been completed: the USAID-financed Demographic and Health Survey (DHS, 1992), an ODA-financed health financing survey (1991), and the Tanzanian National Nutrition Survey (1991). The DHS and nutrition surveys collected data on specific nutrition, demographic, and health outcomes, as well as use of some social services. However, they do not contain essential economic information about the household or detailed data on the use of the education system.¹

¹ In 1994 the Tanzania Bureau of Statistics completed a Welfare Monitoring Survey of approximately 7,000 households. The data are expected to be ready for analysis by the end of 1994.

THE QUESTIONNAIRE

1. **Contents of the Questionnaire.** The main objective of the survey was to obtain data on the use of, and spending on, the social sectors. The primary emphasis was on education and health--the areas in which the major gaps in availability of data were identified. The survey was divided into five major components, each of which was further subdivided, as described below:²

I. Individual Questionnaire

- A. Household Roster;
- B. Information on parents of children between 7 and 15 years of age;
- C. Information on the utilization of, and spending on, education services;
- D. Information on the utilization of health services for those reported ill in the month previous to the interview;
- E. Information on the utilization of, and spending on, prenatal care, delivery, and family planning.

II. Contingent Valuation Questions on:

- A. Primary Health Facility (includes modules allowing respondents to assess desired characteristics of facilities, to reveal their willingness to pay for health services, and to provide information on the available health care facilities);
- B. Primary Education Facility (includes modules allowing respondents to assess desired characteristics of schools and curriculum, to reveal their willingness to pay for education services, and to provide information on the available schools and curriculum);
- C. Demand for Child Spacing;
- D. Envisaged, Required Income Level.

III. Household Questionnaire

- A. Land and livestock ownership;
- B. Household income and economic activities;
- C. Annual expenditures;
- D. Monthly expenditures;
- E. Weekly expenditures;
- F. Housing characteristics and expenditures;
- G. Mortality: deaths in the last 12 months.

IV. Community Price Questionnaire

² Annex 2 contains both the English and Swahili version of the questionnaire.

- V. Cognitive Test:³ The cognitive test was adapted from Sabot's test (Knight and Sabot, 1990) and consists of a shorter version of his long test. The test was administered to 500 children between the ages of 7 and 15 that were present in the home at the time of the interview.
2. The design of the questionnaire took advantage of the huge volume of work done on household questionnaires over the past decade. The next paragraphs highlight areas in which this survey is different from the Social Dimensions of Adjustment (see Delaine *et al.* 1992) or Living Standard Measurement-type of surveys (e.g. Ainsworth *et al.* 1992; Grosh 1991). Where appropriate, a summary of the reasons for the difference in approach is also presented.
3. **The Yellow Card.** A yellow-colored Household Roster card was included in the questionnaire. The interviewer had to copy some of the information--age, gender, and name--from the household roster onto this yellow card. The removable Household roster card was then used throughout the rest of the questionnaire for reference as to which members of the household were eligible for particular sections and what their ID numbers were.
4. **Income Questions.** It was decided that our survey, unlike the majority of the surveys we reviewed, would not include data to be used to estimate income levels. Gathering complete and accurate income data is a very time-consuming activity in countries where few receive wages and the majority are self-employed and engaged in non-market activities. In analysis, income questions are difficult to use; monetary incomes are often calculated to be negative; and, when much of the sample works outside the formal market economy, these problems are compounded. Given our time and budget constraints it was not logical for us to try to measure income.
5. We did include a few questions about sources of income. In this section, our objective was not to gather the information necessary to estimate income levels, but rather to ascertain the main economic activities in which the household engaged, and how the household ranked them in order of importance. For those growing crops, we wanted to establish the relative importance of each crop and the proportion of it that was marketed.
6. **Expenditures Section.** The three principal issues which had to be resolved regarding the expenditure section were as follows:
- (i) How to organize the expenditures in terms of levels of observation: individuals or households, and the recall period;
 - (ii) Whether to split consumption expenditure and consumption of home production, or to ask them in the same question; and
 - (iii) How to take into account seasonality of food consumption.
7. Accurate and complete measurement of expenditures is essential. To maximize the accuracy of the information gathered, different types of expenditures were organized into different levels of observation, depending on the consumption item for which we were measuring expenditures. For example, better estimates of consumption are likely to be obtained by adapting the period of recall to the frequency

³ The cognitive test was adapted from R. E. Sabot's test that was used in the late 1970's in Tanzania.

of purchasing the good. Accordingly food expenditures had a week-long recall period, while education expenditures had a one-year recall period. For some items, we gathered information at the individual level--e.g. education and health--and for some, at the household level--e.g. housing and utilities. For food items, we split consumption expenditure and consumption of home production. For items such as education, for which expenditures are more likely to be cash expenditures, we did not split them. However, we explicitly included the following instructions with the expenditure questions: "Please include contributions of labor and other non-cash items, which we will convert to shillings."

8. To address the problem posed by seasonality of consumption, we phrased the question as "During a **typical** week this past year, did anyone in this household acquire or spend money on..." Also it must be kept in mind that not all consumption expenditures are recorded in Part 3, Sections C, D, and E of the Consumption Section. Expenditures on education can be obtained from Section 1, Part C: Schooling, while housing expenditures were included in Section 3, Part F: Housing.

9. The survey asked only a few questions on ownership of durables and none regarding their acquisition cost or present value. There is evidence from Grosh, Zhao, and Jeancard (1995) that information on durables does not change the results of welfare ranking. This is another area in which we chose to shorten the questionnaire and the length of interview.

10. **The Contingent Valuation Questions.** One of the distinguishing features of the HRDS survey is the use of contingent valuation questions to better understand households' perception and valuation of some services available to them, which characteristics they value the most, and how far actual levels of provision are from desired levels. A three-step process was followed. In the first step, the respondent was given 20 chips (or shillings), representing a budget constraint. The enumerator then showed him or her a card with 5 pictures, representing 5 characteristics of a health facility (or of a primary school). The respondent was asked to allocate the 20 shillings among the 5 characteristics. In the second step, the enumerator asked how much the respondent was willing to pay for a visit to a health facility--or, in the case of education, for one year of tuition in a primary school--that matched the most important characteristics for the respondent. In the third and final step, the respondent was asked to characterize the closest health facility (and closest primary school) in terms of the five characteristics that he/she was previously asked to rank. This information should provide a picture of what households consider important in primary health and education services, and of how well the available facilities meet the household's desires. We tried to select characteristics that designers of health and education services tend to emphasize as important. For health, we mixed characteristics of public and private goods.

11. **Respondent Rules.** Different respondents were chosen for different sections to increase accuracy. For some topics, information from proxy or household respondents will be less accurate or less applicable (e.g. the contingent valuation questions on child spacing from a 10-year-old boy). In the header on each page of the questionnaire, there is a space to identify the respondent. This information can be useful for some types of analysis in which it is important to know characteristics of the specific respondent. In the introduction to each section, the preferred respondent is explicitly stated. Accordingly, for Section 1, Part A, the head of the household is the preferred respondent; but in Part D, the preferred respondent is "Each eligible individual, with assistance of the head of household if necessary."

12. **The Community Questionnaire.** We asked community questions to all selected households in a cluster because of the statistical principle that multiple answers to the same question provide better information, on average, than asking only a single "principal informant" these questions. Also, for some questions--e.g. distance to the closest village health center--it is important to obtain answers from each

household. In some rural clusters in Tanzania, houses can be 15 miles apart. Therefore important inter-cluster inequalities may be neglected if not all households are questioned. The price questions, because they do not vary much across households in a cluster, were answered either by a principal respondent or through inspection in the local markets or shops.

STEPS IN CONDUCTING THE SURVEY

1. **Major Tasks and Timetable.** The survey effort began in mid-June, 1993, with a trip to Tanzania. At that time, we ascertained that a household survey was merited but that the fieldwork would have to be completed by January, 1994, to be useful for sector and project work. A first draft of the survey instrument was prepared in late June/early July, 1993, as a joint effort of Tanzanians and members of the World Bank Mission. Field work began in September, 1993. We received the full set of data from the survey by early March, 1994. The timetable below shows the dates of major activities and the persons involved.

<i>Task</i>	<i>Responsible Person</i>	<i>Date</i>
Management of the Project	C. Griffin	June 1, 1993-October 31, 1994
Development of Survey Instrument, Interviewer's Manual, Supervisor's Manual, Instructions for Sample Design and Selection, and Forms to Re-interview the Households.	L. Ferreira, C. Griffin, M. Ainsworth, M. Ravicz, L. Goodhart, H. Amani, P. Rawal.	June 15 - August 15, 1993
Sampling and Fieldwork Strategy Developed	Prof. H. Amani, C. Griffin, and L. Ferreira	July 1 - 31, 1993
Hire and Train Data Gathering Team	Prof. H. Amani, with support from L. Ferreira, C. Griffin, and the World Bank Resident Mission in Dar es Salaam.	August 2 - September 5 and September 11 - 18, 1993
Pre-Test of the Questionnaire		August 13-15, 1993 (First) August 22-24, 1993 (Second)
Survey Translation		August 10 - September 6, 1993
Field Work		September 5-10 and September 19, 1993 - January 31, 1994
Data Entry	Dr. A. Swai (Muhimbili Hospital, Dar es Salaam, Tanzania)	September 20 - January 31, 1994
	Office Remedies (Virginia, USA)	February-March, 1994
Data Cleaning and Coding of Character Variables	Lynn Tsoflias, Joyce Bentzman, and Luisa Ferreira	May 10 - December 31, 1994

2. **Financial Support.** The survey was jointly funded by the British Overseas Development Administration (ODA), Japan, and the World Bank.

3. **Identification of Local Project Management Leader/Survey Firm.** During the mission in June/July, 1993, Prof. Amani, of the Economics Department of the University of Dar es Salaam, agreed to lead the survey effort in Tanzania. Accordingly, a plan for the field work was drafted. Under Prof. Amani's project leadership, a team of 33 enumerators (university students) and 5 field supervisors (university faculty) was hired.

4. **Development of Sampling Strategy.** The HRDS is national in scope and uses all the 222 clusters of the National Master Sample (NMS) maintained by the Bureau of Statistics as its sampling frame.⁴ Two NMS clusters were not surveyed because of weather conditions. For example, Nyamburi village in the Mara region was inaccessible. Heavy rains had washed away a bridge 8 kms (14 miles) from the village. All household surveys conducted by the Bureau of Statistics (e.g. Agricultural Sample Survey since 1986/87, Labor Force Survey in 1990/91) have used the framework of the NMS. This permits obtaining estimates at the national level and by area: rural, Dar es Salaam (DSM), and other urban towns. The current NMS covers 222 clusters: 100 rural villages representing the rural areas, and 122 Enumeration Areas (EAs) representing the urban areas. Fifty-two EAs are from the capital city, itself, 40 EAs are from the nine municipalities (Arusha, Dodoma, Moshi, Tanga, Morogoro, Iringa, Mbeya, Tabora, and Mwanza), and 10 EAs are from the remaining regional headquarters.

5. **Selection of households and non-response.**

Household selection was done in the field. In each cluster the team supervisor would first obtain the list of ten-cell leaders from the local authorities, and then, from each ten cell-leader, the list of households belonging to his/her cell. Each household was assigned a unique number, and then, using a table of random numbers, randomly selected. In each cluster, a list of about 30 households was then obtained, the last households in the list being alternates. With the collaboration of local authorities, the field workers were able to have an almost 100 percent response rate, except for the cases in which no member of the household was present for interviewing, and returning to the household was not feasible. Refusals to cooperate were rare. In those cases--absent households or refusals--new

Table 1: Regional (Rural and Urban) Sampling

Region	Rural	Urban	Total
Dodoma	100	80	180
Arusha	118	121	239
Kilimanjaro	124	154	278
Tanga	132	167	299
Morogoro	88	120	208
Coast	79	88	167
Dar es Salaam	0	1127	1127
Lindi	84	50	134
Mtwara	114	44	158
Ruvuma	69	49	118
Iringa	124	128	252
Mbeya	174	153	327
Singida	82	41	123
Tabora	99	72	171
Rukwa	59	56	115
Kigoma	83	35	118
Shinyanga	153	54	207
Kagera	193	24	217
Mwanza	163	192	355
Mara	97	63	160
Mainland Tanzania	2135	2818	4953
Zanzibar	127	104	231

⁴ For more information on the NMS see "The National Master Sample" a technical report by The Bureau of Statistics, President's Office, The Planning Commission, published in June, 1993.

households were drawn from the list of alternates.

6. The survey covered a total of 4,953 households in the 20 regions of Mainland Tanzania: 2,135 rural and 2,818 urban (see **Table 1**). In a second stage, the survey was extended to Zanzibar, where 230 households, in 24 clusters, were interviewed.

7. In each cluster, between 20 and 25 households were targeted to be interviewed.⁵ These households were randomly selected. For a household belonging to village i , the household sampling weight (factor from household level to the national level) is defined according to the following expression: $w_h = w_i^* \frac{1}{n_i}$,

where n_i gives the sample size in village i , and w_i^* is the NMS village weight (factor that expands from the cluster level to the national level).

8. **Development of Survey Instrument.** The first draft of the household survey was developed in English in July, 1993. Training of enumerators, based on this draft, began on August 2, 1993. The month of August was devoted to training the enumerators and pre-testing the questionnaire. The first pre-test of the questionnaire took place in mid-August. The household questionnaire was almost completely precoded to eliminate coding errors and time delays. A category labeled "other: specify" was added to several questions. For those questions for which answers were not mutually exclusive, we precoded them with letters, rather than numbers, to allow for unambiguously coding of multiple answers. To minimize non-sampling errors, the questionnaire was in a form that reduced to a minimum the number of decisions required of interviewers while in the field. In anticipation of pages becoming detached from the questionnaire, every page contained a space for the household number and the last digit of the cluster code. Despite the fact that questions were written exactly as they were supposed to be asked by the interviewer, interviewers were granted some flexibility to give the interview greater semblance to a conversation, rather than an inquisition.⁶

9. **Pre-Test of Questionnaire.** The "pre-pre-test" of the questionnaire (August 16, 1993) was done only to discern whether the questions were understood, how long the administration of the survey required, whether all responses had been anticipated, which sections needed to be stressed during the training, etc. In this pre-pre-test, each questionnaire required an average of 4 hours to complete, far longer than the planned 1.5 hour maximum. The survey was consequently shortened and streamlined.

10. The true pre-test was conducted in two different types of clusters: Ubungu ward in DSM (urban) and Kibaha in the Coast Region (rural) over a period of two days. We chose these clusters because they are representative of two distinct groups, so a broader spectrum of answers and problems with the instrument could be anticipated. In the pre-test each questionnaire required an average of 2.5 hours. After a couple weeks of interviewing, the enumerators became more familiar with the instrument, resulting in their spending an average of 1.5 to 2 hours per questionnaire.

⁵ This target number reflects the trade-off between precision in the estimates, and operational constraints on the completion time of the survey.

⁶ Lower case instructions were to be read aloud to the respondent, while upper case instructions were meant to provide directions to the interviewer.

11. During the pre-test, each supervisor was asked to comment on each interview. The supervisor was asked to pay special attention to questions that seemed to make the respondent uncomfortable, that the respondent had difficulty understanding, or that the respondent seemed to dislike. The supervisor also evaluated which sections seemed to go slowly, had the most difficult questions, or provided insufficient opportunity for a complete response.

12. **Revision of questionnaire.** Given the results of the two pre-tests, several areas for improvement in the questionnaire were identified. Perhaps most importantly, the willingness-to-pay amounts were adjusted. The sample distributions of the maximum willingness-to-pay questions were analyzed, and, based on that analysis, we decided to change some of the values. For example, in the child spacing question, the "pay Tsh 1,000" responses unexpectedly accounted for a large share of the bids. Thus, we provided the option of paying more by introducing "pay Tsh 50,000" and "pay Tsh 25,000" as answer choices. For the other contingent valuation sections--health and education--the first pre-test determined that there was also a large lumping of responses at the high end of the scale. We adjusted the ranges accordingly, although there remains some lumping at the high end in the final data.

13. We also changed the order of the sections. Based on the pre-test and judgment of the field workers, we decided to first ask the questions in the individual section, then the contingent valuation questions, then the household questions. Because the respondents enjoyed the contingent valuation questions so much, this decision helped increase interest in the questionnaire and re-energized the respondent before proceeding with the household questions--the last part of the questionnaire. The final survey instrument, incorporating all of the changes dictated by the pre-tests and other expert advice, was completed on September 12, 1993.

14. **Translation.** Translation of the survey instrument was a joint effort of the enumerators and supervisors. Given the specific characteristics of the Kswahili language, this was a much better approach than asking one translator to translate from English to Kswahili, and another one to translate from Kswahili to English. The "group" translation, involving those who would ask the questions, was intended to avoid different interpretations of the same question and achieve uniformity. In this way the enumerators were able to better convey the message/objective of each question.

15. The majority of the interviews were conducted in swahili. In very few cases, because no one in the selected household could speak swahili, the need arose to use interpreters.

16. Our initial plan called for the field work to start no later than August 29. However, unforeseen circumstances, including both financial and logistical problems, delayed the first field trip. Both the money and the materials were available by September 6, and five of the six teams left for Tanga region on that day. Initially we had planned to have the sixth team based full-time in Dar es Salaam; however, tighter time constraints imposed by the above and subsequent delays eventually made it necessary to send the sixth team into the field as well, as detailed below.

17. **First "Field Trip."** From September 6 through September 10, an experimental survey trip was conducted. Five teams went to Tanga region, and one team remained in Dar-es-Salaam. The major findings from this trip were as follows:

- a. On average each questionnaire required 2.5 hours to complete. The following were fixed time costs of entering each cluster: identification of boundaries in the case of urban

clusters; authorization from the local authorities; identification of the ten cell leaders;⁷ listing; identification and selection of the households; and required travel to each home. The teams could then proceed with the interviews. In total, each enumerator could perform only about 3 interviews per day; in the rural villages it became dark after six p.m., and no electricity was available.

- b. Given the length of the questionnaire and our experience in the field, we decided to drop the section entitled "TIME USE DURING SCHOOL YEAR." This section proved to be very time-consuming, and respondents became tired quickly, which was likely to have adverse effects on the following section of the questionnaire, "ACUTE ILLNESSES."
- c. After this first week of "real" field work, some fine tuning in the survey instrument was necessary. Also, a need to expose the enumerators to further training was recognized, as several major areas of weakness became evident. At the same time, we started producing 4,500 copies of the final questionnaire. Once again a delay in the transfer of funds delayed the start of field work. The first tranche of the payment was not received until September 18. Accordingly, all the contracts were modified, and the field work was replanned to start on September 19.
- d. **Additional Training.** Four major problems surfaced which indicated a need for more training. The enumerators did not fully understand the following concepts:
 - (i) In-kind income/expenditure. Subsistence farmers with no other economic activity would appear in the completed questionnaire as having no source of income, and as having no expenditure on those items for which no cash payment had actually been made.
 - (ii) Household membership and how to report expenditures for members who had also been "members" of other households within the previous 12 months (e.g. newlyweds).
 - (iii) Direct sponsorship and indirect subsidies to students in the education section.
 - (iv) Use of the yellow card.
- e. The enumerators received further training (September 12 through September 16). In reviewing the questionnaires, we also determined that it was necessary to reinterview some of the households.
- f. The performance of one supervisor and two enumerators did not meet our quality standards, and they were dismissed. This fact, together with the loss of one supervisor for

⁷ When the idea of ten-cell leadership was first introduced, every group of ten households would have a "leader" to solve any problems and disputes that would arise among households, to keep demographic data, and to provide the next level structure with household information as required. Today, in some villages or wards, we can find some ten-cell leaders with 20 households, and in some others with just 5. Under the multiparty system, each party can put its candidate to compete for the leadership through voting.

health reasons, required replanning of the field work. However, the dismissal of the supervisor and enumerators, combined with the promotion of four enumerators to assistant supervisor positions, positively affected the motivation and performance of the whole team.

18. **Field Trip Preparation.** Initially the field work team was composed of 6 supervisors and 33 enumerators. After the Tanga trip, the team was reduced to 4 supervisors and 31 enumerators. This final team of 31 enumerators comprised students and recent graduates from the University of Dar es Salaam, who were primarily economics and business majors.

19. Given the constraint that 21 of the 31 enumerators were students who needed to be back in Dar es Salaam no later than October 12, the following was decided:

- (i) All teams would work outside Dar es Salaam for the period of September 18 through October 12. Initially we had planned that 1 team (comprising 8 enumerators) would interview in Dar es Salaam, while the other 5 teams would go upcountry.
- (ii) After the students returned from the countryside, they would start interviewing in Dar es Salaam, on a part-time basis, while the 10 graduate enumerators finished the clusters outside Dar es Salaam.
- (iii) Each 2 supervisors had 15 or 16 enumerators, rather than 5, as initially planned. As this imposed an additional burden on the supervisors, 4 enumerators, based on their superb performance during the first week of field work, were promoted to Assistant Supervisors. Other than interviewing, they were responsible for a preliminary check of each questionnaire for mistakes, unanswered questions, wrong skip rules, inconsistencies, etc., before the supervisor proceeded with the final check. Nonetheless, the final word on the quality of the questionnaire remained in the supervisors' hands. Given the logistics of the field work, it was essential to have each and every questionnaire thoroughly checked before the team left the cluster.

20. **Survey Preparation.** In each cluster the research team needed to obtain permission from the authorities before beginning the interviews. Previous to the start of the field work, we requested permission from the Government Statistician to conduct interviews using the NMS clusters as the sampling framework. The research clearance was obtained from the university rather than from the government because the team that carried out the field work was from the university. There were certain procedures that had to be followed before beginning the interviews. First, in each region, one had to obtain permission from the regional headquarters to conduct the interviews. Second, the district authorities had to issue a research clearance, to be later presented to the ward secretary. Often, the ward secretary introduced the team to the village authorities. In the villages, the teams were introduced to the households either by the village secretary or by the ten-cell leaders.

21. **Survey Materials.** Each enumerator was given an "Interviewer's Manual," two sets of cards and 20 chips for the Bidding Games, and a set of supplies consisting of a briefcase, pencils, eraser, notebook, calculator, red pen, clip board, and binder clips. Also, each enumerator had a supply of the cognitive tests, yellow cards with and without printed ID numbers, and blank questionnaires. It was the enumerator's responsibility to administer the household questionnaire and the cognitive test.

22. The main mission of the supervisor was to check the work of the other team members at all levels, guarantee that interviews in the field proceeded satisfactorily, maintain high quality standards, review the completed questionnaires, and reinterview a sub-sample of the households.⁸ As the number of completed questionnaires was viewed as an indicator of interviewer performance, it was conceivable that interviewers would indicate an incorrect response to questions requiring follow-up questions in order to expedite the process. For example, if the household had no income from crop production, then the interviewer would not need to ask questions regarding the type of crop grown.⁹ If a household were revisited, the Supervisor would use a "mini-questionnaire," containing a set of such questions. Every household questionnaire was checked by the supervisor after the interview was completed. At the end of each day, the supervisor and the enumerators discussed particular cases covered, problems faced, questions that proved to be difficult, etc. The supervisors' other tasks included arranging logistics, random selection of households in each cluster, assignment of households to each enumerator, obtaining clearance from several administrative layers, and completion of the price questionnaire. To perform these tasks, each supervisor received, in addition to materials received by the enumerator, a **Supervisor's Logbook**. It included the following:

- i. Supervisor's Manual.
- ii. Price questionnaire to be administered in each cluster by the Supervisor.
- iii. Sample Design and Selection:
 - (a) Selection of the clusters was based on the National Master Sample maintained by the Bureau of Statistics (1988 Census). Each supervisor was provided with a set of maps for each cluster.
 - (b) Within each cluster, households were randomly sampled. Instructions to sample households were given to each team supervisor. These instructions included a set of random numbers tables.
- iv. Forms to re-interview households.
- v. Forms to be completed for each cluster with the population of the cluster and its number of households. This information is essential to construct the weights to be used in the analysis.
- vi. General set of instructions on how to assign a unique identifier to each household.
- vii. For the first week of the field work, the supervisor's logbook also included a spreadsheet in which the results from the contingent valuation questions were to be entered.

23. **Data entry.** Two possible firms in Tanzania were identified to perform the data entry. Both were asked to present cost estimates. Based on the cost estimates and the conditions proposed by each firm, it

⁸ A complete development of the interviewers' and enumerators tasks and responsibilities can be found in the respective manuals.

⁹ Despite the fact that the supervisor was present in several interviews, to the best of our knowledge, none of the households were re-interviewed. However, it should be kept in mind that the supervisor went with the team to every cluster.

was decided to contract the services of Dr. Swai at the Data Processing Center at the Muhimbili Hospital. The team was composed of one supervisor (Dr. Swai), 12 data entry people working in shifts, and 1 liaison at the World Bank Resident Mission in Dar es Salaam.¹⁰

24. At the start of the field work, the interviewing and data entry were nearly simultaneous. Each team was in charge of mailing the completed questionnaires to the Resident Mission, which then delivered them to Dr. Swai. However, because the field work slowed down after classes began (only the 10 non-student enumerators continued interviewing) and only returned to full speed in mid-December (again with a full team of 31 interviewers), the flow of questionnaires was not nearly as smooth as planned.¹¹ We had great difficulty keeping track of the survey effort during November and December due to communication problems between the nodes: the field, the data entry people, the Resident Mission, and Washington. Given that the household survey was an essential building block for the Social Sector Review, and because breakdowns in the data entry system caused grave concern about the timeliness and quality of the data to be made available to us, we decided to have the questionnaires shipped to the U.S. Several possible firms were identified, asked to present cost estimates, and to propose a schedule of activities. Based on the information provided, a contract was awarded to Office Remedies. To minimize data entry mistakes, the data were entered twice, by different people. This ensures over 99% accuracy.

25. As previously mentioned, the questionnaire that was used during the Tanga trip included an additional question on "TIME USE DURING SCHOOL YEAR." This information was entered at the World Bank headquarters using the SURVEY Program.¹²

26. **Major Tradeoffs Made in Survey Design.** Ideally any single person/household should not be subject to questioning for longer than 1.5 hours. People easily become bored, tired, and impatient, which negatively affects the quality of the data. Also, given the logistics of the field work, the need to have the data collected before the rainy season (together with a target of 5,000 households) required that each interview should, on average, take no longer than 2 hours. Consequently, we chose not to collect information on income and to use expenditures alone to classify households by economic well-being. After two pre-tests, two sections included in the initial survey instrument were deleted to shorten the interview: time allocation and detailed facility/community data. We chose not to administer the Raven's test at that time, and the cognitive test was shortened considerably. During the first pre-test, each questionnaire required, on average, four to five hours. We also dropped individual questions after combing the instrument for low priority questions. After the questionnaire was streamlined and field workers gained several weeks of experience, the average interview required approximately 1.5 to 2 hours.

27. In rural clusters, households enjoyed being interviewed, and they did not mind a lengthy questionnaire. Everybody seemed to enjoy the contingent evaluation questions and to be very serious about

¹⁰ Ms. Elizabeth Sakaya was in charge of keeping a log of all the questionnaires received from the field by express mail and delivering them to Dr. Swai at Muhimbili Hospital. The logs were also to inform headquarters of the status of the field work including the number of households and the number of clusters completed.

¹¹ As noted earlier, the student enumerators were supposed to continue interviewing in Dar es Salaam during class time. Here the payment would be per questionnaire, thus creating an incentive to interview as many households as possible. However, contrary to what was planned, in the absence of Professor Amani's supervision, the supervisors who stayed in Dar es Salaam did not continue with the field work. If things had gone as planned, we could have finished the field work one month earlier.

¹² The SURVEY program was designed by the Centers for Disease Control, for data entry.

them. In the urban clusters, a lengthy questionnaire was not as well received by the respondents.

28. Whether the issue is to analyze the effectiveness and the impact of projects, to design those projects, or to provide information to increase the usefulness of dialogue with the government, it is very important that the survey results be made available quickly. We want to maximize the quality of the data used, but time is a very important constraint. Given the law of large numbers, statistical estimates become more precise if more households and clusters are included rather than if a small number of households are interviewed to perfection. In this survey the data were available for analysis, and results made available less than one year after the preparatory work began, and about three months after the last interview. Despite the fact that not everything developed as planned,¹³ we achieved a good balance between timeliness of data production and quality of information.

29. **The Zanzibar Household Survey.** The Revolutionary Government of Zanzibar expressed a desire to have a Household Survey conducted in Zanzibar so that they might have the same type of information that had been gathered for the Mainland. The early experience with the Tanzania Household Survey and the more recent experience with the additional field work in Zanzibar helped us to conclude that many of the time costs are fixed--traveling to the site, securing clearance from the appropriate authorities, training the interviewers, etc. Once the interviewers are familiar with the survey and the supervisors are familiar with the mechanics of the work, the new survey can be conducted quickly. In fewer than 10 days of field work, a group of six experienced interviewers, one supervisor, and a member of the Bureau of Statistics of the Republic of Zanzibar interviewed 230 households in 24 different clusters.

30. **Major problems with the Survey:**

- i. **Delay in receiving funds and materials from Washington .** We operated in the nearly impossible situation of raising money to pay for the survey while it was underway. In addition, the time schedule placed incredible stress on World Bank procurement and payment mechanisms. If we had had more time, all of these processes could have been arranged well in advance. As this was not the case, it was all done on an emergency basis. We caused incredible stress to the system, everyone around us, and ourselves. The delays were usually short, but they caused a few important and avoidable delays in the survey. The goodwill and flexibility of our colleagues, especially of Professor Amani, made it possible to succeed nearly on schedule. However, none of us would advocate repeating the experience in this manner.
- ii. **Quality Control by Supervisors.** After each interview the supervisor was expected to spend some time checking and editing each questionnaire. This is particularly important in the rural areas, and in urban clusters far from Dar es Salaam, where the costs of returning to the cluster are high. The household questionnaire even included one page (page 4B) for the supervisor's check. We noticed that, in some questionnaires, the supervisor's check was not very strict. The majority of mistakes that we handled during the data cleaning and coding phase could have been avoided had the supervisor been more careful with the checking of each questionnaire in the field. However, we will now be able to

¹³ Contrary to what was planned, we did not re-interview households. Also, we only obtained price questionnaires for 07 clusters. For the remaining clusters, the price questionnaires were either lost or not completed.

improve the manuals by specifically noting many of the problems we found. Data entry in the field, or close to the clusters, would probably reduce such problems tremendously. Also, contrary to what was planned the supervisors did not re-interview any of the households.

- iii. **Price Questionnaires.** We only obtained price questionnaires for 70 clusters, out of 222 planned. For the remaining clusters, the prices questionnaires were either lost or not completed. The remaining data still seem useful to obtain some information on price variation within and across different regions.
- iv. **Two Forms.** During the first week of the field-work we used a questionnaire that included a section on time usage for some members of the household, and had a different ordering of questions in other sections. The existence of two forms caused additional problems during the data entry phase.

LESSONS FOR THE FUTURE

1. What Should We Have Done Differently?

- The printing of the questionnaires should have been done commercially, rather than using the university duplicating facilities.
- The fieldwork operations should have been decentralized in six or seven regional headquarters.
- The authorities at the regional, district, and village levels should have been contacted prior to the beginning of the survey work.
- We chose not to enter data in the field because we could not guarantee the logistics. Data entry was centralized in Dar es Salaam. We should have considered options such as regionalized data entry, partial-entry in the field, etc.
- We should have employed multiple contractors for data entry to increase the competitive element in this phase, as data entry can be a serious bottleneck.
- The household identifier number should have been written on every page of the questionnaire during the printing phase, not in the field.
- We should have standardized every element to the degree possible to reduce costs and increase speed.
- Each questionnaire should have allowed for the insertion of more pages for those questions that were to be asked of all household members. This would have minimized the need to use more than one questionnaire per household.
- We should have included a mechanism to ensure that the supervisor and enumerators would receive lower compensation if there were more than a certain number of mistakes in each questionnaire.
- **Training of Supervisors:** The principal authors of the questionnaire should have been present during the training of the supervisors, who then trained the enumerators. Supervisors were trained for a short period of time, which may have been inadequate. This may be the reason that, after the first week of field work, enumerators needed to be exposed to an additional week of training. They knew the "mechanics of the questionnaire," but the majority of them misunderstood the underlying economics.
- The supervisors' training should have more strongly emphasized their role in quality control of the field work.
- **Training of Enumerators:** Enumerator training should have included more practice interviews and more days of training in small groups, with active participation by trainees.
- We should have hired a surplus of enumerators during the training period and deferred the decision whether or not to retain them until after the pre-test. This would have provided a larger pool from which to select, as well as providing incentives for the trainees to excel during the training period.
- **Transportation:** Ideally each team should have had a third car just to transport questionnaires, or even better, each team should have been smaller. Allowing the ratio of

field supervisors to interviewers to be higher would have provided more time in the field for revision and correction of the work of each interviewer.

- We paid inadequate attention to the bridging function of moving surveys from the field into the data entry stage and to monitoring data entry. This should have been treated as a full-time, professional job. This person could have checked each questionnaire sent from the field, edited it, and only then sent it on for data entry. If this person had known a statistical package, the data could have been checked immediately after entry for inconsistencies and extreme values, and it could have been compared against the questionnaires. Also, this person could have provided some support to the Data Entry team.

2. The early experience with the Mainland fieldwork taught us some lessons that we were able to implement in the fieldwork for the survey that was conducted subsequently in Zanzibar. "In undertaking the HRDS in Zanzibar, we did not encounter as many problems as we did in the Mainland. We did not experience problems in supervision, logistics or in the health condition of the enumerators. [...] On lessons learned, one is quite obvious, namely: If a Survey is well planned and employs well trained and experienced enumerators, its chance of success is very high.[...]. Lastly it is necessary to point out that having someone on the team who knows and is quickly acceptable to people [a Zanzibari that knew the location of the clusters was hired] in the chosen clusters makes it very easy to administer the survey." (Adapted from "Final Report on the Human Resource Development Survey in Zanzibar" by Prof. H. K. R. Amani, July 1994.)

3. **Additional Questions.** While analyzing the data, we reviewed the questionnaire and identified other useful questions. It should not be forgotten that the design of our questionnaire was heavily determined by the data already available (we did not want to repeat others' efforts), the type of analysis desired, and the projects that we had in mind. In other settings, with different purposes and/or objectives in mind, major adjustments in the questionnaire might be required. Among the set of questions that we should have included in our questionnaire are the following:

- a. A variant of the household roster for all members of the household. Part 1, Section B, contains the information on mothers and fathers of children, ages 7-15, in the household. This section should have been expanded to include more information regarding family ties within the household. The traditional household roster only gives the relationship to the head and is not useful in some cases when it is desirable to have more information on the household structure.
- b. In the health section, we designed the questionnaire to capture the number of facilities that were visited, and to gather information on the characteristics of the facilities and levels of expenditures made there. We should have added a question asking why people choose to go to a second practitioner, a third, and so on.
- c. Who is the major earner(s) in the household? Corresponding to what we did in the "sources of income" and "crops" sections, we should have asked the respondent/household to rank the relative importance of each member as a contributor to household income.
- d. We should have asked about the desired number of children.
- e. Time diary: In the first week of field work (Tanga region), the household questionnaire still included a question on allocation of time for those members between the ages of 7 and

25. Future analysis of this data on 300 households will, hopefully, tell us more about the quality and usefulness of the time allocation data collected using a recall period. In the future, a time diary should be used to collect information on time allocation, as it is likely that there is a significant loss of accuracy with a recall period.

- f. The survey questions regarding improvements in the community in the last two years (e.g roads, water supply, electricity) should have also asked whether the improvements have benefitted the community or the household (more than the average, about the average, less than the average).
- g. In both the health and family planning sections, we should have asked "how long did the consultation last?" The idea is that, in some places, there is no waiting time because people spend only a short time with the physician. This, together with the waiting time, would have given some additional information on the quality of the service being provided. In addition, we should have included a question in the family planning section on whether the source of supplies/consultation was government or non-government (this problem was fixed in the Zanzibar questionnaire).

4. **Plans for The Future.** We believe that this survey contributed substantially to the infrastructure available for future efforts of this type, both at the University of Dar es Salaam and at Muhimbili Hospital. It is also part of our agenda to make certain that this survey will contribute to the development of the human capital required to analyze the survey and apply it to policy making in Tanzania. For that purpose we are preparing a proposal for a six-month series of lectures and seminars to build capacity in household economics, survey analysis, and policy applications. A series of joint papers produced during these seminars, and other papers using the household survey, will be presented at an International Workshop to be held in Tanzania. We believe that this two-part project will facilitate fully analyzing the survey in a short period of time.

 - **Survey (English version)**
 - **Price Questionnaire**
 - **Sabot's Test (English version)**

Some General Comments on the File Structure and Contents

1. The questionnaire is divided into three sections, and each section is divided into several parts. The files are organized as follows:

DATA SET	SECTION	QUESTIONS IN SURVEY	PAGES
HR.DAT	Survey execution notes	1	
HR1.DAT	1	2-24	5-9
HR2.DAT	1	25-32	11
HR3.DAT	1	33-83	13-18
HR4.DAT	1	84-126	20-25
HR5.DAT	1	127-175	27-32
HR6.DAT	2	1-46	35-40
HR7.DAT	2	47-116	42-49
HR8.DAT	2	117-183	51-58
HR9.DAT	3	1-11	59-60
HR10.DAT	3	13-20	61
HR11.DAT	3	21-61	63-65
HR12.DAT	3	62-140	67-77
HR13.DAT	3	141-151	78-79
HR14.DAT	3	152-198	80-84
HR15.DAT	3	200-207	85-86
HR16.DAT	Sabot's Test	1-16	
HR17.DAT	Price Questionnaire	1-20	
DISTRICT.DAT	District Data		

2. Identification variables. In each file, there is adequate information to uniquely match, as appropriate, all individual, household, and cluster observations. HHN (household number) is imbedded in **HR1 thru HR16** data files and uniquely identifies each household. Within each household, each member has a unique identification number--ID--in the individual level files (e.g., HR1 dataset). In the HR dataset, each cluster can be uniquely identified by the CLUSTER code together with the REGION code.
3. Rules for Linking Files. Files HR, HR6, HR7, HR8, HR9, HR10, HR11, HR12, HR13, HR14, and HR15 are household level files and can be merged together by using the variable HHN (household number). Files HR1, HR2, HR3, HR4, HR5, and HR16 are individual level files, and can be uniquely matched by using simultaneously the variables HHN and ID. Files HR17 and DISTRICT are uniquely identified by the simultaneous use of the variable REGION and CLUSTER, and can be merged with file HR, which contains these two variables.
4. The variable name consists of the question number prefixed by:
 - I for section 1 (Questions for Individuals)
 - C for section 2 (Contingent Valuation Questions)
 - H for section 3 (Questions for the Household)
5. For questions with two parts a suffix indicates the part:
 - D for distance

C for code
A for amount
U for unit
T for Time

For example, Question 168 on Section 3, Part F (Household Questions on Housing), asks for the amount of time that "it takes to walk from your house to this road" and for the unit that the respondent is using. Thus, we have two variables: H168A for amount of time and H168U for unit used. A value of 30 for H168A, and of 1 for H168U means that it takes the household 30 minutes to walk from the house to the road.

6. For questions requiring time and minutes, the minutes were entered as a decimal part of the time. Hence, 1.4 equals 1 hour and 40 minutes.
7. Variables starting with RE and ending with a number are the respondent ID codes. The number indicates the starting page for the sections answered by the respondent. For example, variable RE13 (file HR3) contains the ID code of the household member that answered the questions in Section 1, Part C (pages 13-18).
8. New codes: If a household member's response was OTHER/SPECIFY, the interviewer recorded the full response on the survey tally sheet. On the basis of this information, some new codes were added to the existing variables. They are:

FILE	VARIABLE	CODE	DESCRIPTION
3	I39	3	waiting for results
3	I41	Y	waiting for results
3	I41	1	got married/got pregnant
3	I41	Z	handicapped
4	I89	0	shop/first aid
4	I92	0	shop/first aid
4	I95	12	shopkeeper
4	I100	0	shop/first aid
4	I103	12	shopkeeper
5	I167	5	did not pay
5	I169	14	traditional method
11	ITEM	615	fruit
11	ITEM	355	outside contribution/ family member
11	CA	99	no harvest this year
11	RA	99	no harvest this year
12	ITEM	141	salt/sugar/tea leaves
14	H159C	4	flat rate (water)
14	H160C	4	flat rate (water)
14	H197	5	pagan

9. Other codes were added to the variables throughout the questionnaire. The data entry program fills all blanks with -9. A value of -6 is different from a **value of -9** (default value). A **value of -6** indicates an out of range value, a skip rule error, or a hard copy error. When a skip rule applies and a question was left blank, the variable will have a value of -9. For example, in section 1, question 13 "What is the highest grade in school that ...[NAME] completed", if a respondent gave a response

of 1, he should have answered question 14 "What type of primary school...". If a respondent did not give an answer to question 14 or the interviewer did not record the response to that some question, then a value of -9 was entered automatically by the data entry program, and no modification was made, though this is a mistake. However, if the respondent gave a response of 1 to question 13, then he should not have answered question 15 "What type of Secondary School..." and the interviewer should not have recorded a response. If a response was recorded then a modification was made and a value of -6 was assigned. In summary, a -6 value always corresponds to a mistake, while -9 corresponds to a blank value in the questionnaire, whether it should have been filled by the enumerator with a "valid" value, or not.

10. File 8--the Contingent Valuation Section: Child Spacing--a value of 99 for the variable FOS indicates that more than 1 child spacing form was completed for the household.
11. Some members gave more than one response for questions that only required one. For example, question i169 asked for one type of birth control used. A member gave two answers, 56. This indicates the member uses both condoms (5) and spermicides (6) . Thus, the following variables could contain more than one response:

FILE	VARIABLES
4	I90, I95, I103, I111
5	I145, I169, I172,
14	H164, H166A, H166B.

12. **Weighted Estimates.** In the HR.DAT file, the variable household weight--WEIGHT_H--was added. This variable is based on the National Master Sample of Tanzania, and on the number of households in each cluster. When the weights are summed over all the households in the dataset they will add to the number of households in Tanzania. When producing weighted statistics using the household weight variable one will obtain nationally representative statistics. Thus, to obtain statistics that mimic census-type results, in any statistical package use the **WEIGHTING OPTION**. For example, in STATA to compute the means write "**summ list of variables [w=weight_h]**".
13. The sampling framework allow obtaining statistics broken down by location--rural, urban (non-Dar es Salaam), and Dar es Salaam. The variable RURAL containing the code can be found in file HR. In files with records at the household level weighted basic statistics will reflect the number of households. In files with individual level records, weighted statistics will reflect the population of the country. Note that the variable WEIGHT_H times the family size will yield a variable whose sum will be the population of Tanzania. For more details on the National Master Sample framework see Bureau of Statistics publication on the National Master Sample (The National Master Sample, Technical Report, Bureau of Statistics, The United Republic of Tanzania, June 1993; the publication is also available in Volume II of the Project Completion Report).
14. **Variables added and dropped**
 - a. Variable I170A was added to File 5, the Prenatal and Delivery Services Section. This question on family planning facility type was only asked for the survey conducted in Zanzibar, so for the households in the mainland the variable will have a value of -6.

- b. Some modifications were done during the data cleaning phase. The shamba and garden variables H1S, H2S, H3S, H1G, H2G, H3G were replaced with variable H1, H2, H3, H4, which represent a combination of the number of shambas and gardens owned and used. In file 10, the Livestock Section, variable H12 was dropped because only those households with livestock were included in the file.
- c. In File HR1--the Household Roster--those listed that were not household members were removed.
- d. File HR4--Acute Illness Section--contains only those household members who were sick, or the information was incorrect or left blank, i.e., when question 84 takes the values 1,2,3,-9,-8, or -6.
- e. File HR9--the Land Section--only households who use or own shambas, gardens or livestock were included in the file.
- f. File HR15--the Mortality--contains only households with members that have died in the in the last 12 months. Thus, variables H199 and H200 were dropped from the dataset.
- g. File HR--variable rural takes 4 values:
 - 1=Rural (Mainland Tanzania)
 - 2=Urban (Mainland Tanzania and Zanzibar)
 - 3=Rural-coral (Zanzibar)
 - 4=Rural-non coral (Zanzibar)

Problems

- 15. District Data. No district data was collected for the NJOMBE district. The district data was collected in 1993 and was the most recent data available. In the cases where the year is known it is indicated in the variable label. The district data for Dar es Salaam is not broken down by district, except for population.
- 16. Outliers. Extreme values for variables like distances, time, expenditures, area of land owned, or number of livestock owned were left in the dataset. They were compared against the paper copy to double check for any data entry errors. This way, each researcher can decide how to handle this problem and how to use the information.
- 17. Problems with Membership. According to the instructions in the survey, interviewers were supposed to ask question 7 (age) and subsequent questions (Part 1--file HR1) only for members, where household membership was defined according to the requirements in question 6. There were about 550 individuals that had been coded as non-members, despite the fact that according to questions 4 (number of months in residency) and 5 (away at secondary school) they should have been classified as members. Since they were originally coded as non-members, no data were collected for those individuals. We left them in the HR1 dataset. This way, each researcher can decide how to handle this problem and how to use the information.

Basic Statistics for the Raw Data Sets¹
